

# Manacher's algorithm

Idea: using Mirror property

Assume: for  $a_0 a_1 a_2 \dots a_{n-1}$

$P[i]$  is the longest palindrome centered at  $i$ 's  
diameter (i.e.  $a_{i-P[i]} a_{i-P[i]+1} \dots a_{i+P[i]-1} a_{i+P[i]}$ )

Assume  $P[0] \sim P[4]$   
is known

$a_0 a_1 a_2 a_3 a_4 | a_5 a_6 a_7 a_8$

$C$

How to effectively  
use mirror property  
to compute  
 $P[5] \sim P[7]$

define  $i' = M(i, c)$  as  
the mirror index of  $i$   
around  $c$

$$\begin{aligned} i' = M(i, c) &\Rightarrow c - i' = i - c \\ &\Rightarrow i' = 2c - i \end{aligned}$$

There are 3 cases for  $P[i']$ :

- Case 1:  $i + P[i'] < r$
- Case 2:  $i + P[i'] = r$
- Case 3:  $i + P[i'] > r$

Case 1:  $i + P[i'] < r$

We know that apparently  $P[i] \geq P[i']$ .  
 Let's check if  $\bar{i}$  can expand beyond  $P[i']$

Assume  $a_{\bar{i} - P[i'] - 1} = a_{\bar{i} + P[i'] + 1}$

let's mirror  $\bar{i} - P[i'] - 1$  and  $\bar{i} + P[i'] + 1$

$$\Rightarrow a_{M(\bar{i} - P[i'] - 1, C)} = a_{2C - (\bar{i} - P[i'] - 1)}$$

$$= a_{\underline{2C - \bar{i} + P[i'] + 1}}$$

$$\Rightarrow a_{M(\bar{i} + P[i'] + 1, C)} = a_{\underline{2C - \bar{i} - P[i'] - 1}}$$

$$= a_{\bar{i}' - P[i'] - 1}$$

$$\text{So } a_{\bar{i}-P[i']-1} = a_{\bar{i}+P[i']+1}$$

$$\Leftrightarrow a_{\bar{i}'+P[i']+1} = a_{\bar{i}'-P[i']-1}$$

This tells us that  $i'$  can be further expanded, contradict our assumption that  $P[i']$  is the longest palindrome diameter.

$$\Rightarrow P[\bar{i}] = P[i']$$

$$\text{Case 2: } \bar{i} + P[i'] = r$$

apparently,  $P[\bar{i}] \geq P[i']$ , but we need to check if it is possible  $P[\bar{i}] > P[i']$

We want to check

$$a_{\bar{i} + P[\bar{i}'] + 1} \stackrel{?}{=} a_{\bar{i} - P[\bar{i}'] - 1}$$

let us mirror the above equation around  $C$

$$\begin{aligned} a_{M(\bar{i} + P[\bar{i}'] + 1), C} &= a_{\underline{2C - \bar{i} - P[\bar{i}'] - 1}} \\ &= a_{\bar{i}' - P[\bar{i}'] - 1} \end{aligned}$$

$$\begin{aligned} a_{M(\bar{i} - P[\bar{i}'] - 1), C} &= a_{\underline{2C - \bar{i} + P[\bar{i}'] + 1}} \\ &= a_{\bar{i}' + P[\bar{i}'] + 1} \end{aligned}$$

Observe that

$a_{\bar{i} + P[\bar{i}'] + 1}$  and  $a_{\bar{i}' - P[\bar{i}'] - 1}$   
equality is unknown because

$$\bar{i} + P[\bar{i}'] + 1 > r \text{ and } \bar{i}' - P[\bar{i}'] - 1 < M(r, c)$$

$\Rightarrow$  we have no information to use by mirroring!

Therefore, in case 2, we have to expand  $r$  until we encounter an inequality!

Case 3:  $\bar{i} + P[\bar{i}'] > r$

Apparently,  $P[\bar{i}] \geq P[\bar{i}']$ , but we still need to check if  $P[\bar{i}] > P[\bar{i}']$

Let's assume  $a_{\bar{i} + P[\bar{i}'] + 1} = a_{\bar{i} - P[\bar{i}'] - 1}$

let us mirror it around  $c$ :

$$a_{M(\bar{i} + P[\bar{i}'] + 1, c)} = a_{2c - \bar{i} - P[\bar{i}'] - 1} \\ = a_{\bar{i}' - P[\bar{i}'] - 1}$$

$$a_{M(\bar{i} - P[\bar{i}'] + 1, c)} = a_{2c - \bar{i} + P[\bar{i}'] - 1}$$

$$= a_{i'} + p[i'] + 1$$

observe that

$$\underline{a_{i + p[i']} + 1} = a_{i - p[i']} - 1$$

and  $a_{i + p[i']} + 1 = \underline{a_{i'} - p[i']} - 1$

and  $a_{i - p[i']} - 1 = a_{i'} + p[i'] + 1$

$$\Rightarrow a_{i + p[i']} + 1 = a_{i'} - p[i'] - 1$$

This tells us that  $P[c]$  can be further expanded!

Contradicts that  $P[c]$  already is the maximum

$$\Rightarrow P[i] = r - i$$
